# nlmrt-vignette

John C. Nash

August 11, 2012

### Background

This vignette discusses the R package nlmrt, that aims to provide computationally robust tools for nonlinear least squares problems. Note that R already has the nls() function to solve nonlinear least squares problems, and this function has a large repertoire of tools for such problems. However, it is specifically NOT indicated for problems where the residuals are small or zero. Furthermore, it frequently fails to find a solution if starting parameters are provided that are not close enough to a solution. The tools of nlmrt are very much intended to cope with both these issues.

The functions are also intended to provide stronger support for bounds constraints and to introduce the capability for **masks**, that is, parameters that are fixed for a given run of the function.

nlmrt tools generally do not return the large nls-style object. However, we do provide a tool wrapnls that will run either nlxb followed by a call to nls. The call to nls is adjusted to use the port algorithm if there are bounds constraints.

# 1 An example problem and its solution

Let us try an example initially presented by (Ratkowsky 1983) and developed by (Huet et al. 1996). This is a model for the regrowth of pasture. We set up the computation by putting the data for the problem in a data frame, and specifying the formula for the model. This can be as a formula object, but I have found that saving it as a character string seems to give fewer difficulties. Note the "" that implies "is modeled by". There must be such an element in the formula for this package (and for nls()). We also specify two sets of starting parameters, that is, the ones which is a trivial (but possibly unsuitable) start with all parameters set to 1, and huetstart which was suggested in (Huet et al. 1996). Finally we load the routines in the package nlmrt.

```
ones <- c(t1 = 1, t2 = 1, t3 = 1, t4 = 1)  # all ones start
huetstart <- c(t1 = 70, t2 = 60, t3 = 0, t4 = 1)
require(nlmrt)

## Loading required package: nlmrt

## Loading required package: minpack.lm

## Loading required package: optimx

## Loading required package: numDeriv</pre>
```

Let us now call the routine nlsmnqb (even though we are not specifying bounds). We try both starts.

```
anmrt <- nlxb(regmod, start = ones, trace = FALSE, data = pastured)</pre>
print(anmrt)

## [21] "8.37588355893792"
```

Note that the standard nls() of R fails to find a solution from either start.

```
anls <- try(nls(regmod, start = ones, trace = FALSE, data = pastured))
print(strwrap(anls))

## [1] "Error in nlsModel(formula, mf, start, wts) : singular"
## [2] "gradient matrix at initial parameter estimates"

anlsx <- try(nls(regmod, start = huetstart, trace = FALSE, data = pastured))
print(strwrap(anlsx))

## [1] "Error in nls(regmod, start = huetstart, trace ="
## [2] "FALSE, data = pastured) : singular gradient"</pre>
```

In both cases, the nls() failed with a 'singular gradient'. This implies the Jacobian is effectively singular at some point. The Levenberg-Marquardt stabilization used in nlxb avoids this particular issue by augmenting the Jacobian until it is non-singular. The details of this common approach may be found elsewhere (Nash 1979). ?? Do we want a page ref?

There are some other tools for R that aim to solve nonlinear least squares problems. We have not yet been able to successfully use the INRA package nls2. This is a quite complicated package and is not installable as a regular R package using install.packages(). Note that there is a very different package by the same name on CRAN by Gabor Grothendieck.

#### 2 The nls solution

We can call nls after getting a potential nonlinear least squares solution using nlxb. Package nlmrt has function wrapnls to allow this to be carried out automatically. Thus,

```
awnls <- wrapnls(regmod, start = ones, data = pastured)
print(awnls)
## Nonlinear regression model
    model: yield \tilde{t}1 - t2 * exp(-exp(t3 + t4 * log(time)))
##
##
     data: data
      t1 t2
                t3
## 69.96 61.68 -9.21 2.38
##
   residual sum-of-squares: 8.38
## Number of iterations to convergence: 0
## Achieved convergence tolerance: 8.33e-08
cat("Note that the above is just the nls() summary result.\n")
## Note that the above is just the nls() summary result.
```

### 3 Problems specified by residual functions

The model expressions in  ${\sf R}$  , such as

```
yield \sim t1 - t2*exp(-exp(t3+t4*log(time)))
```

are an extremely helpful feature of the language. Moreover, they are used to compute symbolic or automatic derivatives, so we do not have to rely on numerical approximations for the Jacobian of the nonlinar least squares problem. However, there are many situations where the expression structure is not flexible enough to allow us to define our residuals, or where the construction of the residuals is simply too complicated. In such cases it is helpful to have tools that work with R functions.

Once we have an R function for the residuals, we can use the safeguarded Marquardt routine nlfb from package nlmrt or else the routine nls.lm from package minpack.lm (Elzhov, Mullen, Spiess, and Bolker 2012). The latter is built on the Minpack Fortran codes of (Moré, Garbow, and Hillstrom 1980) implemented by Kate Mullen. nlfb is written entirely in R, and is intended to be quite aggessive in ensuring it finds a good minimum. Thus these two approaches have somewhat different characteristics.

Let us consider a slightly different problem, called WEEDS. Here the objective is to model a set of 12 data points (density y of weeds at annual time points tt) versus the time index. (A minor note: use of t rather than tt in R may encourage confusion with the transpose function t(), so I tend to avoid plain t.) The model suggested was a 3-parameter logistic function,

```
y_{model} = b_1/(1 + b_2 exp(-b_3 tt))
```

and while it is possible to use this formulation, a scaled version gives slightly better results

```
y_{model} = 100b_1/(1 + 10b_2exp(-0.1b_3tt))
```

The residuals for this latter model (in form "model" minus "data") are coded in R in the following code chunk in the function shobbs.res. We have also coded the Jacobian for this model as shobbs.jac

```
shobbs.res <- function(x) {
    # scaled Hobbs weeds problem -- residual
    # This variant uses looping
    if (length(x) != 3)
       stop("hobbs.res
     <- c(5.308, 7.24, 9.638, 12.866, 17.069, 23.192, 31.443,
       38.558, 50.156, 62.948, 75.995, 91.972)
    tt <- 1:12
   res <- 100 * x[1]/(1 + x[2] * 10 * exp(-0.1 * x[3] * tt)) -
shobbs.jac <- function(x) {</pre>
   # scaled Hobbs weeds problem -- Jacobian
    ji <- matrix(0, 12, 3)
   tt <- 1:12
   yy <- exp(-0.1 * x[3] * tt) # We don't need data for the Jacobian
    zz < -100/(1 + 10 * x[2] * yy)
    jj[tt, 1] <- zz
    jj[tt, 2] <- -0.1 * x[1] * zz * zz * yy
    jj[tt, 3] <- 0.01 * x[1] * zz * zz * yy * x[2] * tt
   return(jj)
```

}

With package nlmrt, function nlfb can be used to estimate the parameters of the WEEDS problem as follows, where we use the naive starting point where all parameters are 1.

```
st <- c(b1 = 1, b2 = 1, b3 = 1)
ans1 <- nlfb(st, shobbs.res, shobbs.jac, trace = FALSE)</pre>
print(ans1)

```

This works very well, with almost identical iterates as given by nlxb. (Since the algorithms are the same, this should be the case.) Note that we turn off the trace output. There is also the possibility of interrupting the iterations to watch the progress. Changing the value of watch in the call to nlfb below allows this. In this code chunk, we use an internal numerical approximation to the Jacobian.

```
cat("No jacobian function -- use internal approximation\n")

## No jacobian function -- use internal approximation

ans1n <- nlfb(st, shobbs.res, trace = FALSE, control = list(watch = FALSE)) # NO jacfn
print(ans1n)

```

Note that we could also form the sum of squares function and the gradient and use a function minimization code. The next code block shows how this is done, creating the sum of squares function and its gradient, then using the optimx package to call a number of minimizers simultaneously.

```
shobbs.f <- function(x) {</pre>
   res <- shobbs.res(x)
   as.numeric(crossprod(res))
shobbs.g <- function(x) {</pre>
   res <- shobbs.res(x) # This is NOT efficient -- we generally have res already calculated
   JJ <- shobbs.jac(x)</pre>
   2 * as.vector(crossprod(JJ, res))
require(optimx)
aopx <- optimx(st, shobbs.f, shobbs.g, control = list(all.methods = TRUE))</pre>
## Attaching package: 'RumminCRAN'

## [1] TRUE
```

We see that most of the minimizers work with either the analytic or approximated gradient. The 'CG' option of function optim() does not do very well in either case. As the author of the original step and description and then Turbo Pascal code, I can say I was never very happy with this method and replaced it recently with Rcgmin from the package of the same name, in the process adding the possibility of bounds or masks constraints.

## 4 Converting an expression to a function

Clearly if we have an expression, it would be nice to be able to automatically convert this to a function, if possible also getting the derivatives. Indeed, it is possible to convert an expression to a function, and there are several ways to do this (references??). In package nlmrt we provide the tools model2grfun.R, model2jacfun.R, model2resfun.R, and model2ssfun.R to convert a model expression to a function to compute the gradient, Jacobian, residuals or sum of squares functions respectively. We do not provide any tool for converting a function for the residuals back to an expression, as functions can use structures that are not easily expressed as R expressions.

Below are code chunks to illustrate the generation of the residual, sum of squares, Jacobian and gradient code for the Ratkowsky problem used earlier in the vignette. The commented-out first line shows how we would use one of these function generators to output the function to a file named "testresfn.R". However, it is not necessary to generate the file.

First, let us generate the residuals. We must supply the names of the parameters, and do this via the starting vector of parameters ones. The actual values are not needed by model2resfun, just the names. Other names are drawn from the variables used in the model expression regmod.

```
# jres <- model2resfun(regmod, ones, funname='myxres',</pre>
# file='testresfn.R'
jres <- model2resfun(regmod, ones)</pre>
print(jres)
## function (prm, yield = NULL, time = NULL)
##
       t1 <- prm[[1]]
       t2 <- prm[[2]]
##
       t3 <- prm[[3]]
##
       t4 <- prm[[4]]
##
       resids <- as.numeric(eval(t1 - t2 * exp(-exp(t3 + t4 * log(time))) -
##
           yield))
##
## }
## <environment: 0xa40166c>
valjres <- jres(ones, yield = pastured$yield, time = pastured$time)</pre>
cat("valjres:")
## valjres:
print(valjres)
## [1] -7.93 -9.80 -17.59 -21.33 -38.35 -55.11 -60.73 -63.62
## [9] -66.08
```

Now let us also generate the Jacobian and test it using the numerical approximations from package numDeriv.

```
jjac <- model2jacfun(regmod, ones)</pre>
print(jjac)
## function (prm, yield = NULL, time = NULL)
## {
       t1 <- prm[[1]]
       t2 <- prm[[2]]
t3 <- prm[[3]]
       t4 <- prm[[4]]
       localdf <- data.frame(yield, time)</pre>
       jstruc <- with(localdf, eval({
           .expr1 <- log(time)
           . expr4 <- exp(t3 + t4 * .expr1)
           .expr6 <- exp(-.expr4)
           .value <- t1 - t2 * .expr6 - yield
.grad <- array(0, c(length(.value), 4), list(NULL, c("t1",</pre>
##
##
           ##
##
##
##
##
##
            .value
      }))
##
##
       jacmat <- attr(jstruc, "gradient")</pre>
##
       return(jacmat)
## }
## <environment: 0xa5394f4>
# Note that we now need some data!
valjjac <- jjac(ones, yield = pastured$yield, time = pastured$time)</pre>
cat("valjac:")
## valjac:
print(valjjac)
                     t2
                                t3
   [1,] 1 -2.372e-11 5.804e-10 1.275e-09
##
   [2,] 1 -2.968e-17 1.130e-15 2.981e-15
##
##
    [3,] 1 -1.617e-25 9.232e-24 2.811e-23
    [4,] 1 -8.811e-34 6.706e-32 2.235e-31
##
    [5,]
          1 -2.615e-50 2.986e-48 1.116e-47
##
    [6,] 1 -5.123e-68 7.938e-66 3.209e-65
          1 -4.230e-75 7.243e-73 3.001e-72
##
    [7,]
    [8,] 1 -2.304e-83 4.385e-81 1.863e-80
   [9,] 1 -5.467e-94 1.174e-91 5.130e-91
# Now compute the numerical approximation
\label{local_state} $$Jn \leftarrow jacobian(jres, ones, , yield = pastured$yield, time = pastured$time)$$ cat("maxabsdiff=", max(abs(Jn - valjjac)), "\n")$
## maxabsdiff= 3.774e-10
```

As with the WEEDS problem, we can compute the sum of squares function and the gradient.

```
ssfn <- model2ssfun(regmod, ones) # problem getting the data attached!
print(ssfn)

#### 5 Using bounds and masks

The manual for nls() tells us that bounds are restricted to the 'port' algorithm.

lower, upper: vectors of lower and upper bounds, replicated to be as long as 'start'. If unspecified, all parameters are assumed to be unconstrained. Bounds can only be used with the '"port"' algorithm. They are ignored, with a warning, if given for other algorithms.

Later in the manual, there is the discomforting warning:

The 'algorithm = "port"' code appears unfinished, and does not even check that the starting value is within the bounds. Use with caution, especially where bounds are supplied.

We will base the rest of this discussion on the examples in man/nlmrt-package.Rd, and use an unscaled version of the WEEDS problem.

First, let us estimate the model with no constraints.

```
require(nlmrt)
\mbox{\tt\#} Data for Hobbs problem
ydat <- c(5.308, 7.24, 9.638, 12.866, 17.069, 23.192, 31.443.
   38.558, 50.156, 62.948, 75.995, 91.972)
tdat <- 1:length(ydat)</pre>
weeddata1 <- data.frame(y = ydat, tt = tdat)</pre>
start1 <- c(b1 = 1, b2 = 1, b3 = 1)  # name parameters for nlxb, nls, wrapnls.eunsc <- y ~ b1/(1 + b2 * exp(-b3 * tt))
anlxb1 <- try(nlxb(eunsc, start = start1, data = weeddata1))</pre>
print(anlxb1)

```

Now let us see if we can apply bounds. Note that we name the parameters in the vectors for the bounds. First we apply bounds that are NOT active at the unconstrained solution.

```
# WITH BOUNDS
startf1 \leftarrow c(b1 = 1, b2 = 1, b3 = 0.1) # a feasible start when b3 <= 0.25
anlxb1 <- try(nlxb(eunsc, start = startf1, lower = c(b1 = 0,
   b2 = 0, b3 = 0), upper = c(b1 = 500, b2 = 100, b3 = 5), data = weeddata1))
print(anlxb1)

## [1] 2.587
```

We note that nls() also solves this case.

Now we will change the bounds so the start is infeasible.

```
## Uncon solution has bounds ACTIVE. Infeasible start
anlxb2i <- try(nlxb(eunsc, start = start1, lower = c(b1 = 0,
    b2 = 0, b3 = 0), upper = c(b1 = 500, b2 = 100, b3 = 0.25),
    data = weeddata1))
print(anlxb2i)</pre>
```

Both nlxb() and nls() (with 'port') do the right thing and refuse to proceed. There is a minor "glitch" in the output processing of both knitR and Sweave here. Let us start them off properly and see what they accomplish.

```
## Uncon solution has bounds ACTIVE. Feasible start
anlxb2f <- try(nlxb(eunsc, start = startf1, lower = c(b1 = 0,</pre>
   b2 = 0, b3 = 0), upper = c(b1 = 500, b2 = 100, b3 = 0.25),
   data = weeddata1))

##
## Algorithm "port", convergence message: both X-convergence and relative convergence (5)
```

Both methods get essentially the same answer for the bounded problem, and this solution has parameters b1 and b3 at their upper bounds. The Jacobian elements for these parameters are zero as returned by nlxb().

Let us now turn to **masks**, which functions from nlmrt are designed to handle. Masks are also available with packages Rcgmin and Rvmmin. I would like to hear if other packages offer this capability.

```
## TEST MASKS

## 6 Brief example of minpack.lm

Recently Kate Mullen provided some capability for the package minpack.lm to include bounds constraints. I am particularly happy that this effort is proceeding, as there are significant differences in how minpack.lm and nlmrt are built and implemented. They can be expected to have different performance characteristics on different problems. A lively dialogue between developers, and the opportunity to compare and check results can only improve the tools.

The examples below are a very quick attempt to show how to run the Ratkowsky-Huet problem with nls.lm from minpack.lm.

```
require(minpack.lm)
anlslm <- nls.lm(ones, lower = rep(-1000, 4), upper = rep(1000,
    4), jres, jjac, yield = pastured$yield, time = pastured$time)
## anlslm from ones
print(strwrap(anlslm))
    [1] "c(NaN, NaN, NaN, NaN)"
   [3] "NaN, NaN, NaN, NaN, NaN, NaN)"
   [6] "The cosine of the angle between 'fvec' and any column"
   [7] "of the Jacobian is at most `gtol' in absolute value.'
   [8] "list(t1 = 3, t2 = 2.3723939879224e-11, t3 ="
    [9] "5.8039519205899e-10, t4 = 1.27525858056086e-09)"
## [10] "3"
## [11] "c(17533.3402000004, 16864.5616372991, NaN,"
## [12] "1.112549661455e-308)"
## [13] "NaN"
anlslmh <- nls.lm(huetstart, lower = rep(-1000, 4), upper = rep(1000,
    4), jres, jjac, yield = pastured$yield, time = pastured$time)
cat("anlslmh from huetstart\n")
## anlslmh from huetstart
